Graph: (V, E)Attributed graph: (V, E, A). Node attributes *A*: *Boolean, categorical*, or *numeric*

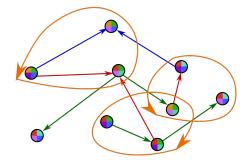

E

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

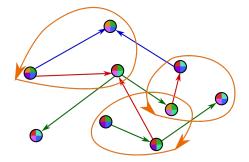

Attributed graph: (V, E, A). Node attributes A: *Boolean, categorical*, or *numeric* Attributed multirelational graph: (V, E, A). E: set of different edge relations

イロト イヨト イヨト イヨト

Attributed graph: (V, E, A). Node attributes **A**: *Boolean, categorical,* or *numeric* Attributed multirelational graph: (V, E, A). **E**: set of different edge relations Attributed multirelational hyper-graph: (V, R). **R**: set of 1,2,3,...-ary relations (subsumes **A**, **E**)

イロト イヨト イヨト イヨト

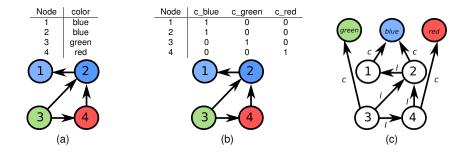

Attributed graph: (V, E, A). Node attributes **A**: *Boolean, categorical*, or *numeric* Attributed multirelational graph: (V, E, A). **E**: set of different edge relations Attributed multirelational hyper-graph: (V, R). **R**: set of 1,2,3,...-ary relations (subsumes **A**, **E**)

Examples for higher arity relations:

3-ary traffic network relation: *on_shortest_path*(location,location,location) 3-ary movie data: *made_contract*(agent,actor,movie)

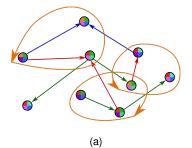

・ロン ・回 と ・ 回 と ・ 回 と

- (a): unary, categorical values
- (b): unary, Boolean/binary values (one-hot encoding)
- (c): binary relation between objects and attribute values materialized as nodes

E

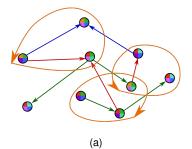

イロト イヨト イヨト イヨト

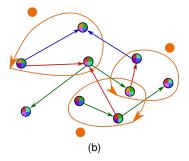

(a): as tuples of nodes

æ

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

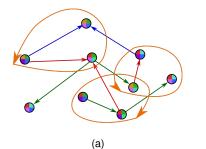

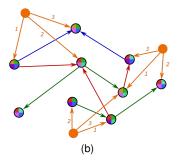

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

- (a): as tuples of nodes
- (b): materialize tuples of nodes;

E

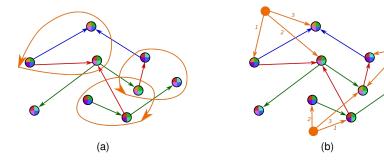

イロト イヨト イヨト イヨト

- (a): as tuples of nodes
- (b): materialize tuples of nodes; connect tuple-nodes with entity-nodes by binary relations

E

- (a): as tuples of nodes
- (b): materialize tuples of nodes; connect tuple-nodes with entity-nodes by binary relations

Boolean values and binary relations are enough in principle (but can be user-unfriendly).

| п | number of nodes/vertices |
|-------------------------------------|--|
| \mathcal{R} | a <i>signature</i> of 1,2,3,ary relation symbols |
| R | specific values of the relations in \mathcal{R} in a graph $G = (V, \mathbf{R})$. |
| $G = (V, \mathbf{R})$ | a graph with node set V , and relations R |
| $\mathcal{G}(V,\mathcal{R})$ | set of all graphs with node set V , and relations in the signature \mathcal{R} |
| $\Delta \mathcal{G}(V,\mathcal{R})$ | set of all probability distributions over $\mathcal{G}(V, \mathcal{R})$ |

Generally assume that $V = \{1, ..., n\}$, and $i, j, ... \in \mathbb{N}$ denote nodes.

Arrays, Matrices, Tensors

Attributes:

n-dimensional array (entries categorical);

Color:

```
(blue, green, ..., red, blue)
```

k different attributes collected in $n \times k$ -dimensional matrix

Binary relations:

 $(n \times n)$ -dimensional *adjacency matrix*;

Friends:

 $\left(\begin{array}{ccccc} 0 & 1 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & 1 \end{array}\right)$

I different relations may be collected in a $(n \times n \times I)$ -dimensional *adjacency tensor*

Logic

(Boolean) relations of all arities:

List positive and negative facts as a *knowledge base* of (negated) *ground atoms* :

c_blue(17) *¬c_red*(21) *friends*(2,53) *¬friends*(53,8)

Knowledge Graphs

Triplet notation

(Barack Oboma, was_born_in, Honolulu)

can be seen as "infix" notation for ground atoms:

was_born_in(Barack Oboma, Honolulu)

◆□▶ ◆□▶ ◆三▶ ◆三▶ ◆□▶ ◆□

Pros and Cons

- **Tensors:** + compact, computationally efficient
 - + support for categorical (attribute) values
 - incomplete data requires '?' or 'NaN' values
- Logic: + coherent treatment of relations of all arities
 - + uniform treatment of positive and negative facts
 - + natural support for incomplete knowledge
 - non binary relations require special treatment
 - non-compact

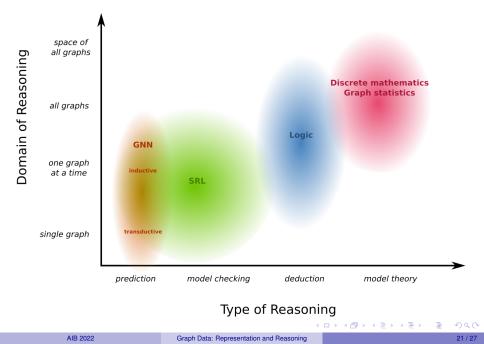

Missing information

- **Tensors:** '0' in adjacency matrix can mean: "there is no edge", or "there is no confirmed edge"
- **Logic:** Positive and negative information are equally definitive. Missing information visible as incomplete knowledge base

To handle semantic asymmetry: *closed-world assumption* used to postulate that all facts not contained in the knowledge base are assumed to be *false* by default.

Reasoning

<ロ> <同> <同> < 同> < 同> < 同> < 同> <

Given: a probabilistic model for the random generation/evolution of graphs.

Question: what is the probability that the graph becomes (stays) connected, as the number of nodes goes to infinity?

► Or many other questions about the global properties of a random graph model.

Mostly (human powered) mathematics, rather than algorithmic reasoning
